

Elsa x Clicks

Agent-native settlement for x402 — splits, attribution, on-chain reputation.

01 STATUS QUO — WHAT X402 ON ELSA LOOKS LIKE TODAY

Elsa ships an agent-native HTTP-402 facade on Coinbase CDP with USDC settlement on Base. The endpoint surface is rich; the settlement surface is flat.

40+

Endpoints live on x402

USDC / Base

Coinbase CDP facilitator

1 wallet

All revenue routes to 0x0D22...ae5b5

The gap: no splits, no referrer attribution, no partner economics. Growing Elsa through third-party agents (MCP wrappers, bots, skill surfaces) today requires off-chain contracts and manual invoicing — friction that scales linearly with partner count.

02 FLOW — BEFORE & AFTER

03 PROPOSAL — THREE BUILDING BLOCKS

MODULE	WHAT IT UNLOCKS FOR ELSA	STATUS
P1 Splitter V4	On-chain revenue splitting for endpoints ≥ \$0.01. Elsa becomes BD-scalable without contracts: third-party agent routes traffic → split executes automatically. New USP for Elsa's own docs: <i>"build on top of us, get paid on every call — no invoices."</i>	Live on Base 0xB7E0016d...3C8
P2 ERC-8004 Identity	Elsa inherits on-chain reputation. Positioning Elsa can adopt in Q2 marketing: <i>"First x402 provider with verifiable agent reputation."</i> Competitors (Bitte, pay-per-call APIs) do not have this.	Live · agentId 45074 Schema V1 published
P3 Yield Router	Buyer-side idle-USDC yield for treasury agents that hold balances between calls. Optional, not in initial scope — surfaced for roadmap awareness.	Live · later phase

04 PILOT — EXECUTE_SWAP , 2 WEEKS, MEASURABLE

SCOPE

- One endpoint: `execute_swap` (universal use case; pattern transfers to the other ~25 endpoints $\geq$ \$0.01).
- ClicksSplitter V4 contract wired into the x402 settlement path. No changes to Elsa's facilitator or SDK surface.
- Default split 80 / 15 / 5 (platform / referrer / agent); configurable per call via header.
- Reference integration shipped as a branch on the Clicks repo. Elsa reviews + merges or cherry-picks.

SUCCESS CRITERIA

- Tx-count on Splitter contract from Elsa-originated calls over 14 days.
- Number of unique referrer addresses (proof the BD loop works).
- Gas overhead as % of call value — target < 5% on calls $\geq$ \$0.01.
- Zero regressions on existing x402 flow (call latency, failure rate).

Next step — clone the branch, try it locally.
